## Electrically powered autonomous vehicle

8/pets

The subject of the present invention is an autonomous  
5 electrically powered vehicle that, to power it, requires a  
significant mass and/or volume of batteries, for example a  
utility vehicle or a public transport vehicle.

10 In spite of the availability of high-performance batteries  
(NiMH, lithium-ion, etc.), it is practically impossible to  
design autonomous vehicles with a large payload capability  
and which are "all electric", because of the problems of  
storing the electricity and of the autonomy or range of the  
vehicle.

15 Furthermore, one serious obstacle to the introduction into  
service of electrically powered autonomous vehicles stems  
from the fact that the technological variation, in terms of  
batteries, is great, complex, expensive, rapidly surpassed  
20 and that the batteries usually require special equipment in  
servicing and repair shops. These constraints are  
incompatible with the need of the operators concerned with  
the transport of individuals and/or goods who need to  
amortize their investments in rolling stock over a period  
25 of between 10 and 20 years.

In order to alleviate the problems of storing electricity  
and of the autonomy or range of the vehicle, it is  
necessary at the present time for vehicles equipped with  
30 such batteries to be equipped with rapid recharging devices  
and/or with electric generator sets stored on board the  
vehicle and able to provide top-up power.

Electrically powered vehicles in which the batteries are  
35 installed on a trailer have also been conceived of, for  
example, in US-A-3 690 397, DE-A-42 05 327, DE-A-41 05 246

or FR-A-2 482 528.

In the case of an electrically powered utility vehicle, it is necessary to be able to have a significant available energy capacity and therefore a sufficient volume of batteries (ranging between 1.5 and 3 m<sup>3</sup>). Technical progress means that the trend is for batteries to supply more power for, sometimes, less weight, but their volume remains more or less unchanged. With lead-acid batteries, a volume of about 2 m<sup>3</sup> corresponds to a mass of about 3 metric tons.

The prior art recalled above discloses small trailers equipped with a single wheel (the aforementioned US-A-3 690 397, DE-A-42 05 327 or DE-A-41 05 246), which solution cannot be read across to the trailer-mounting of a significant mass of batteries as mentioned hereinabove, because that would require the use of a wide (of the order of 400 mm wide) wheel of large (of the order of 1200 mm) diameter, the travel of which, if the wheel were to be a pivoting wheel as in US-A-3 690 397, would considerably reduce the volume available for the batteries. Furthermore, even if the wheel were not a pivoting wheel, as in DE-A-42 05 327, the fact that there was only one wheel would present only disadvantages when applied to a connectable/disconnectable trailer:

- lack of stability when handling,
- the need to provide complicated, bulky and expensive guidance and suspension means,
- the difficulty of maintenance, and
- the difficulty of repairing it should it experience a flat.

The aforementioned DE-A-41 05 246 discloses a trailer in which the, non-steered, wheel or wheels is or are situated between the, also non-steered, wheels of the vehicle and on the same transverse axis. The trailer is guided

transversely but can move up and down vertically, an elastic device being positioned between the vehicle chassis and the trailer and acting as suspension.

5 However, this design operates correctly only under ideal conditions because:

- when the trailer goes over a speed hump, it may be crushed by the chassis of the vehicle; and
- when starting a bend with a cross-fall, the chassis of  
10 the vehicle will become inclined transversely with respect to the trailer and considerable loadings will be applied to the trailer transverse guidance device.

In consequence, the operation of the device that forms the  
15 subject of DE-A-41 05 246 cannot be considered to be reliable.

The prior art (the aforementioned FR-A-2 482 528) also discloses the addition of a trailer, equipped with a two-  
20 wheeled axle, to a utility vehicle, but the size of this trailer is added to that of the vehicle, the result of this being a considerable loss of space when running around and at the depot.

25 Installing the batteries on an independent chassis makes it possible to conceive of forming, at the vehicle depot, a fleet of charged battery chassis for the purposes of exchanging charged battery chassis for battery chassis that are running out of power, but no document in the prior art  
30 either describes or suggests means for making the connecting and disconnecting of the trailer in order to perform such an exchange rapid, particularly when said trailer is situated under the chassis of the vehicle.

35 The invention proposes to meet the needs of the operators in terms of the amortizement of their equipment costs by

exploiting the principle of dissociating the "batteries" part from the actual vehicle, as has already been conceived of in the prior art, but at the same time remedying the disadvantages and shortfalls of said prior art and doing so  
5 by:

- incorporating the batteries volume into the vehicle, that is to say by including the trailer within the perimeter of the vehicle (or allowing it to protrude only slightly), without thereby introducing any  
10 unevenness in the floor of the vehicle, which needs to be a flat floor; and
- allowing rapid interchangeability of trailers (taking around 10 minutes).

15 These objectives are achieved by the invention which applies to utility vehicles comprising, in a way known per se, batteries supported by an independent chassis which is itself equipped with at least one axle fitted with wheels and which is designed to be accommodated in a housing  
20 defined under the chassis of the vehicle, connecting means being provided for connecting the battery chassis and the vehicle chassis, said connecting means comprising, on the one hand, locking means for locking the battery chassis and the vehicle chassis together and, on the other hand, an  
25 interface on the battery chassis side and an interface on the vehicle chassis side including connectors for the transmission of power and/or commands or information.

According to the invention, said interfaces each further  
30 comprise the complementary male and female parts of at least one centering member and of at least one interconnection member, the interface on the vehicle chassis side consisting of a plate independent of said chassis and joined to it at least three points, two of  
35 which are controlled by rams and the third of which adopts the form of a ball joint.

In one practical embodiment, said centering member adopts the form of two complementary male and female parts that interconnect with a taper, and said interconnection member  
5 adopts the form of two complementary male and female parts which interconnect in a cylindrical form, said centering member and said interconnection member advantageously consisting of two distinct parts of the same piece.

10 In the knowledge that the battery chassis has a longitudinal plane of symmetry perpendicular to its axle or axles and a transverse plane perpendicular to said longitudinal plane, the connection device advantageously comprises a pair of interconnection members and a pair of  
15 centering members, which pairs are symmetric with respect to said longitudinal plane. Since one centering member of a pair and one interconnection member of a pair may, here again, consist of two separate parts of the same piece, it will be understood that there may be two such pieces  
20 symmetric on each side of said longitudinal plane.

The male parts of the centering and interconnection members may be provided on that face of the battery chassis that is designed to be connected to the vehicle chassis and the  
25 complementary female parts may be provided on the interface plate, or vice versa.

Whatever the embodiment adopted, by virtue of these interconnection and centering members, the battery chassis  
30 can easily be positioned with respect to the vehicle chassis.

In one embodiment of the invention, the locking member consists of a headed threaded rod which passes through the  
35 battery chassis, in a direction parallel to its longitudinal plane or to its transverse plane, and which

can be secured to the interface plate.

In practice, there may be a pair of such headed threaded rods designed to pass from end to end through the battery chassis and the interface plate, parallel to the longitudinal plane of the battery chassis, and to be held in place by screwing into a nut. Thus, the battery chassis and the interface plate are immobilized between the head of the screws and the nuts, the threaded rods forming through-bolts.

As a preference, the threaded rods are coaxial with said interconnection and/or centering members and pass through them.

As an alternative, there may be a threaded rod designed to pass, parallel to the transverse plane of the battery chassis, through the centering and/or interconnection member(s) and, from one lateral edge to the other, through the interface plate, whereas the complementary parts of said centering and/or interconnection members are coupled, said rod being held in place by screwing into a nut.

Advantageously, the connectors for transmitting power and/or commands or information from the vehicle to the battery chassis are built into said at least one centering and/or interconnection member, and this makes connection faster still, the centering and the interconnection at the same time resulting in the plugging of the male connectors into the female connectors.

As far as the interface plate is concerned, the rams and the ball joint with which it is equipped make it possible to deaden and absorb the variations in alignment or level between the battery chassis and the vehicle chassis which inevitably occur when the assembly is moving along, as a

result of unevennesses of the roadway and the like.

In one particular embodiment of the invention, said rams are slaved to the steering of the vehicle and/or to whether the vehicle is traveling forward or backing-up, so that the behavior of the battery chassis can be influenced from the driving position of the vehicle, something which may prove to be particularly useful when operating the vehicle backwards.

In one advantageous embodiment of the invention, the opposite end of the battery chassis to its interface for connection with the vehicle chassis is roughly convex, when said chassis is viewed from above. Such a geometry is better able to absorb rear impacts.

As far as the vehicle propulsion motor is concerned, this may be situated in the vehicle and, as a preference, an auxiliary reserve of batteries is provided in the vehicle so that the vehicle can be moved around over a short journey when disconnected from the battery chassis.

As an alternative, in order to reduce the cost and weight of the vehicle and facilitate maintenance, the vehicle propulsion motor is carried by the battery chassis, the motor power then being transmitted to the vehicle via a driveshaft. In this case, an auxiliary motor may be incorporated into the vehicle so that, once again, it can be moved over a short distance when the battery chassis is detached from it. If the auxiliary motor is an electric motor, then an auxiliary reserve of batteries needs also to be provided in the vehicle.

As indicated above, the battery chassis is housed in a housing defined under the vehicle chassis. This housing may be defined under the rear end of the vehicle chassis,

making for ease of access for connecting and disconnecting it.

In this case, the battery chassis may lie within the overall outline of the vehicle or protrude from the rear of the vehicle and be equipped with a bumper and/or impact absorption device in its rear part and/or in its connection device. In this way, the battery chassis protects the rear of the vehicle and/or the end of the housing, from impacts.

In one particular embodiment, the battery chassis is equipped with a connection device situated at the rear of the battery chassis. This arrangement allows this end of the battery chassis to be coupled to equipment for handling it, for the purposes of connecting or disconnecting the other end to or from the vehicle chassis.

The battery chassis may furthermore be either equipped with a charger, allowing the batteries to be recharged wherever the charger can be plugged in to an electrical supply (the terminus or an intermediate stop along the line), or support an energy conversion device able to recharge the batteries. This device may be an alternator operated by a combustion engine or inertia flywheels, and this amounts to equipping the chassis with an electrical generator set capable of recharging the batteries on demand and therefore of extending the range of the vehicle.

The invention will be better understood from reading the detailed description hereinafter of the attached drawings in which:

- figure 1 is a schematic depiction of an electrically powered autonomous vehicle according to the invention, without the battery chassis;

- figures 2a and 2b are schematic depictions of the battery chassis according to the invention, seen from the

end for connection to the vehicle chassis (figure 2a), and from the end for connection to the handling equipment (figure 2b);

5 - figure 3 is a schematic depiction of the installing of the battery chassis in the housing of the electrically powered autonomous vehicle of the invention;

- figure 4 is a schematic depiction of the electrically powered autonomous vehicle according to the invention, with the battery chassis in place;

10 - figure 5 is a schematic depiction of the electrically powered autonomous vehicle according to the invention, equipped with a battery chassis according to an embodiment variant;

15 - figure 6 is an exploded perspective view of one embodiment of the battery chassis and of the interface plate, both viewed from the end for connection to equipment for handling the battery chassis;

- figure 7 is a perspective view of the same elements as in figure 6, but seen from the opposite direction;

20 - figure 8 is a partial perspective view of the vehicle chassis, viewed from beneath, with the interface plate in place;

- figure 9 is a view similar to figure 7 but relating to another embodiment of the invention;

25 - figure 10 is a view similar to figure 9 but showing another embodiment of the centering and interconnection members; and

- figure 11 is a perspective and sectioned view of yet another embodiment of the battery chassis.

30

Figure 1 depicts an electrically powered autonomous vehicle 1 comprising a chassis equipped with two axles each fitted with one pair of wheels 2, and the front of which is denoted by Av and the rear by Ar. The vehicle chassis defines, at the rear, a housing 3 situated under a raised cabin part H and designed to accommodate a battery chassis.

35

The vehicle motor is situated between the wheels of the vehicle (under the steps M of the stairs in the embodiment depicted) or, better still, in the wheels themselves (electric motorized wheels are known in the art and there is no need to describe these here). The volume V available on the roof may be used to house cooling devices, on-board computer equipment and/or an additional reserve of power. It is also possible for equipment specific to the use, for example air-conditioning means, alcohol-fired, gas-fired or fuel-fired heating means (in the current state of the art, electric vehicles are not generally electrically heated because of the bulk, weight and cost of the batteries), antennas and other information transmission systems, to be housed here. Arranging these on the roof in this way obviously frees up more useful volume for passengers.

The battery chassis 4 is depicted in isolation in figures 2a and 2b. As can be seen, this is an independent trailer equipped with an axle fitted with a pair of wheels 5 and having, at one of its ends, means 6 of mechanical connection (which will be described in detail with regard to figures 6 to 9) and electrical and electronic means of coupling to the vehicle chassis (figure 2a) and, at its opposite end (figure 2b), means 7 of mechanical coupling to equipment for handling it. The chassis 4 is equipped with a bumper 9. The wheels 5 may advantageously be equipped with braking devices or retarders. Furthermore, the battery chassis is equipped with safety devices and auxiliary means necessary for the correct operation of said batteries, particularly for monitoring and maintaining the temperature and providing ventilation.

Figure 3 depicts the installation of the battery chassis 4 in the housing 3 of the electrically powered autonomous vehicle 1. As can be seen, the battery chassis 4 is connected by its coupling means 7 to equipment 8 handled by

an operator. This equipment 8 pushes the battery chassis 4 into the housing 3 until its mechanical coupling means and electrical coupling means 6 engage with mating means provided in the end of the housing and not depicted in this figure.

Figure 4 shows the battery chassis engaged in the housing 3.

As can be seen, from figure 4, the wheels 5 of the axle of the battery chassis 4 are positioned in the continuation of the wheels 2 of the axles of the chassis of the vehicle 1 so that they run more or less in the wheel marks of the former. It will also be noticed that the overall appearance of the vehicle according to the invention is roughly the same as that of current buses.

In the variant of figure 5, use is made of a chassis 4' which differs from the chassis 4 in that it comprises two axles each of which is fitted with a pair of wheels, such as 5', and in that it is longer than the chassis 4. The chassis 4' therefore protrudes beyond the rear of the vehicle. A lengthened chassis such as this is able to accommodate more batteries and the additional batteries could be supported by larger wheels instead of by more numerous wheels, as depicted here. Of course, one and the same vehicle may, as need be, be equipped with a short or with a long battery chassis, equipped with conventional batteries or fuel cells, without requiring modification.

Moving on to figures 6 to 8, these more clearly show the battery chassis-side interface and the vehicle chassis-side interface. The interface on the battery chassis 4 side consists of the end face 9 of said chassis from which there project the mechanical, electrical and other coupling means, denoted by 6 in the previous figures. The interface

on the vehicle chassis side consists of a plate 10 offering a face 11 designed to accept said coupling means and which is secured to the vehicle chassis by two rams 12 and a ball joint 13 (see figure 8).

5

More specifically, the mechanical coupling means consist, on the battery chassis 4 side, of a pair of male pieces 14 which comprise a tapered region 15 forming a centering member and a cylindrical region 16 forming an interconnection member. These pieces 14 are symmetric with respect to the longitudinal plane of symmetry of the battery chassis 4 labeled X-X'. Corresponding to this pair of male pieces 14 is a pair of cavities 17 with the same geometry provided in the face 11 of the interface plate 10, which face 11 also comprises sockets, such as 18, designed to accept the plugs 19 projecting from the interface and transmitting power together with commands and information.

The battery chassis 4 and the plate 10 are secured together by means of a pair of headed 21 threaded rods 20 which are first of all passed through passages formed in the battery chassis 4 and emerge, on one side, on the opposite face of the chassis to the face 9, at 22 and, on the other side, in the center of the pieces 9, then in passages formed in the plate 10 and which emerge, on the face 11, at 23 and, on the opposite face, at 24, after which the ends of said rods, that is the opposite end to the end comprising the head 21, is screwed into a nut, not depicted.

The length of the rams 12 and of the support 25 of the ball joint 13 easily allows such screwing or unscrewing. Of course, when the battery chassis 4 is disconnected from the plate 10, it is not essential to extract the rods 20 from said chassis.

35

The embodiment depicted in figure 9 differs from the

previous one in that it has just one male centering and interconnection piece 14' positioned on the longitudinal plane X-X' of the battery chassis 4, in that the interface plate 10 is connected to the vehicle chassis by three rams 12 rather than two, and through the means of locking the battery chassis 4 and the interface plate 10 together. This time, use is made of a single threaded rod 20' with a head 21' designed to pass, on the one hand, through the plate 10 via a passage extending from one lateral face 26 thereof to the other and emerging at 27, on the visible face 26 and, on the other hand, when the male centering and interconnection piece 14' is coupled to a corresponding cavity formed in the plate 10, said male piece via a passage formed transversely in said piece and only the opening 28 of which can be seen in figure 9, the opposite end of the rod 20' to the end bearing the head 21' being screwed into a nut, not depicted.

The embodiment depicted in figure 10 differs from that of figure 9 in that the centering and interconnection members belonging to the chassis 4' consist not of a cylindro-frustoconical piece 14' but of a part 29 in the shape of a pyramid frustum which fits into a cavity of corresponding geometry formed on the non-visible face of the plate 10'.

Finally, figure 11 illustrates an embodiment variant of the embodiment 4" of the battery chassis depicted in figure 7: instead of having two long threaded through-rods 20 that can be turned by hand, this variant comprises a pair of short threaded rods 20", each of which can be turned by an electric motor 30 and which are housed in each of the centering and interconnection members 14". Thus, the operations of connecting and disconnecting the battery chassis with respect to the vehicle chassis are quicker and can be commanded from the cab of the vehicle or automated. That furthermore avoids having to have the threaded rods

pass through the entire length of the chassis.

The reference 31 denotes the batteries carried by the battery chassis.

5

Whatever the embodiment adopted, by operating the rams 12 it is possible to alter the adhesion of the vehicle's driving wheels 2: by "raising" the battery chassis using the rams 12, the wheels 5 of said chassis are effectively  
10 relieved of some of their load, and this load is transferred onto said wheels 2.

Furthermore, it will be understood that the mass of the batteries, such as 31, can be spread over the battery  
15 chassis in a way that is balanced with respect to the wheels 5 of said chassis, so as to make this said chassis easier to handle once the chassis has been disconnected from the vehicle chassis.

20 The present invention is not restricted to the embodiments described and depicted. In particular, the motor of the vehicle could itself too be carried by the chassis 4 or 4', in which case an auxiliary motor would be provided in the vehicle so that it can be moved over short distances when  
25 in the configuration of figure 1. Furthermore, the electric vehicle does not necessarily have four wheels as depicted: it must have at least three, and may have more than four. It may in point of fact be a high-capacity vehicle with double or triple axles.

30

Aside from its technical advantages, the solution put forward has one commercial advantage: specifically, by dissociating the batteries and their support from the vehicle, it becomes possible, while still falling into the  
35 same vehicle weight category for regulation purposes, to expand the volume of the passenger space and increase the

number of passengers.
